## EULERIAN MAGIC WORD SQUARES

## LEONARD GORDON

Tucson, Arizona
In the May 1933 Word Ways, Lee Sallows introduced a form of gematria he called wints (word integers), based on the use of the alphabet and a space to express numbers in base 27. (In normal gematria, $A=1, B=2$, etc.) His article included $3 \times 3$ and $4 \times 4$ magic squares made from wints and found by computer search. In May 1996 he presented additional $3 x 3$ squares found by computer search. In the original article, many of the magic constants were wints. This was not true for the later set. Most are simply Euler squares which become magic for any gematria.

An Euler square, also known as a Graeco-Latin square, is an important tool of statisticians and mathematicians. As illustrated in Figure 2, it consists of an nxn array of two-digit numbers, each digit of which is $0,1,2 \ldots$ or ( $n-1$ ). Each units digit appears once in every row and once in every column, as does each tens digit; furthermore, every possible combination of two digits is represented (00,01,02 ... (n-1)(n-1)). Eulerian squares exist for most values of $n$; 6 is a famous exception, proved, as Euler himself conjectured, to be impossible.

The tens digits need not be $0,1,2 \ldots$; they can be any set of distinct numbers such as $22,31,48,921,2882$. The units digits can be similarly generalized, and need not match the tens digits; however they must all have the same number of digits. The construction of Euler word squares is based on this generalization.

I now show how to construct Euler word squares using a computer strictly as an ancillary device. I present two $5 \times 5$ squares for which the magic constant is a wint; I also present one $8 x 8$ square. To start, I constructed the matrix of Figure 1. Starting with a somewhat larger array (which was later reduced) and using my word processor as a chalkboard, I shifted rows and columns to reveal the region of maximum density in the lower right. This region includes 8 rows and 7 columns. Using the letter-groups end, ill, ore, ins, ear, its, are, all to represent the units digits $0,1,2,3,4,5,6,7$ and the letter-groups $\quad, b, f, p, t, w, s h, s p$ to represent the tens digits $0,1,2,3,4,5,6,7$, one converts the $8 \times 8$ Euler square in Figure 2 to the $8 \times 8$ Euler word square in Figure 3. (Since all 3 -letter endings are themselves words, the _ assignment is possible.)

All words implied by Figure 1 are in Merriam-Webster's 10th Collegiate dictionary. Figure 1 allows us to extract many squares of various sizes but it took a full day of trial and error to find one which when taken as a wint square has a magic constant which is aiso a wint. The magic constant for Figure 4 can be found in Answers and Solutions.

In his initial article, Sallows asks for a magic square whose constant is the wint "magic". This required going to the unabridged dictionaries to allow making Figure 5. This square would not have been found by a computer search even if I had used a vocabulary many times as large as Sallows's.

I have been making arrays like Figure 1 for some time. Sets of begin-ning-ending combinations are useful for many puzzles. Figure 6 was in $m y$ notes. Figure 7 is constructed from it. Most of the 7-, 8- and 9-letter words come from unabridged dictionaries.

For ordinary gematria, return to Figure 1. These Euler magic squares are presented in condensed form:
(d,g,r,s,st) $x$ (ags,ale,ate,ash,ill) = word ways journal
(d,g,h,m,r) x (ash,ate,ays,eed,ill) = ross eckler editor (b,f,p,sh,sp) $x$ (ear,ill,ine,ins,ore) = dave morice kickshaws editor (b,h,r,s,w) $x$ (ags,ail,ash,ays,ill) = leonard gordon author
